Define the Worksheet Index Origin - Must Be Done Before Defining These Functions!!!!

ORIGIN := 9

- vec(z): vec takes a single argument and converts it, appropriately, into a vector. In particular, it converts a scalar into a single-element array, and stacks the columns of a matrix into a vector. It works with nested arrays and will also convert range definitions into a vector with the corresponding values. In M13..M15, vec will convert a range variable into a vector, provided that vec is on the right-hand side of a definition.
- This usage is in keeping with use of vec in matrix theory and extended to cover scalars and nested arrays.

• seq(z): seq takes a single argument z and converts it, appropriately, into a vector containing a sequence of values. In particular, it converts a scalar into a sequence of the form 0..z-1, unless z=0 in which case it returns 0 (representing the empty array) otherwise it behaves like vec.

```
seq(x) \equiv \begin{array}{c} \text{ if IsScalar}(x) \\ \parallel & \text{ if } x \\ \parallel & \parallel & \text{ for } k \in \mathbf{ORIGIN} \dots x \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel & \parallel & \parallel & v \leftarrow k - \mathbf{ORIGIN} \\ \parallel &
```

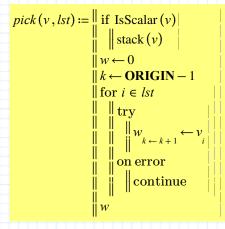

• index(v): creates a vector or a nested vector giving the index of each element of v; useful for plotting v. If v is a scalar, then index returns a list of sequential integers up to and including v-1. If v is a 2D array, then index returns a nested 2-vector containing the row and column indices respectively.

$$index(3) = \begin{bmatrix} 9 \\ 10 \\ 11 \end{bmatrix}$$

Ooh! Cat Skinning Time! We know a song about that, don't we children?

It's nice to be able to pick a set of values from a vector if we know the indices that we want. So let's define a function to do that.

• pick(v,lst): takes a vector v and a list of integer indices lst and returns a vector of the indexed values of v. If v is a scalar pick converts it to a single-element vector (but pick will only return [v] if lst = ORIGIN. Returns 0 if lst does not contain any valid indices.

pick(seq(5),2)=0

$$seq(5)^{T} = [0 \ 1 \ 2 \ 3 \ 4 \ 5]$$

Now we can rewrite Mike's mid index function and combine it with Werner's ORIGIN independence

$$midindex(v) := \begin{vmatrix} k \leftarrow \text{floor}\left(\frac{\mathbf{ORIGIN} + \text{last}(v)}{2}\right) \\ \text{if mod}(\text{rows}(v), 2) = 0 \\ \text{if } k \leftarrow \text{stack}(k, k+1) \end{vmatrix}$$

used floor instead of trunc as trunc rounds to zero, which makes negative ORIGIN behave differently to positive ORIGIN

Which let's us compose a new function that selects the middle indices and passes them straight to pick

$$mid(v) := pick(v, midindex(v))$$

$$\mathbf{ORIGIN} = 9$$

And now get your spoons ready, children. It's --- Proof Of Pudding Time!

$$vl := seq(6) + 11$$

augment
$$(index(vI), vI)^{T} = \begin{bmatrix} 9 & 10 & 11 & 12 & 13 & 14 & 15 \\ 11 & 12 & 13 & 14 & 15 & 16 & 17 \end{bmatrix}$$

$$last(vI) = 15$$

$$midindex(vI) = 12$$

$$v2 \coloneqq seq(7) + 11$$

augment
$$(index(v2), v2)^{T} = \begin{bmatrix} 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 \\ 11 & 12 & 13 & 14 & 15 & 16 & 17 & 18 \end{bmatrix}$$

$$last(v2) = 16$$

$$midindex(v2) = \begin{bmatrix} 12\\13 \end{bmatrix}$$

$$mid(vI) = [14]$$

$$mid(v2) = \begin{bmatrix} 14 \\ 15 \end{bmatrix}$$
